### Global Warming Prediction Index July 2013

**Projected** vs. **measured** temperature trends, Jan 2005 to June 2013 (102 months)

**IPCC projection**

**Satellite trend**

**Over-prediction**

**+0.20 C°**

**-0.02 C°**

**0.22 C°**

**(+2.33 C°/century)**

**(-0.24 C°/century)**

**(2.57 C°/century)**

This month's Index shows IPCC models have over-predicted global warming by 0.22 C° over the 102 months since January 2005 compared with global temperature change measured by the RSS and UAH satellites. The monthly index number is the amount by which the IPCC's central projection has overshoot or undershot the observed temperature trend since January 2005.

This month's graph shows 34 models' projections of global warming since January 2005 in the IPCC's *Fifth Assessment Report* as an orange region. The IPCC's central projection, the thick red line, is that the world should have warmed by 0.20 C° over the period (equivalent to 2.33 C°/century). Yet the mean of the RSS and UAH satellite measurements, in dark blue over the bright blue trend-line, shows global cooling of 0.02 C° (-0.24 C°/century). The models have thus over-predicted warming by 0.22 C° (2.57 C°/century). Warming since 2005 is nothing like as rapid as predicted. The mismatch between the 17 ppmv (202 ppmv/century) rise in the trend on the gray dogtooth CO<sub>2</sub> concentration curve and the lack of warming since 2005 is striking.
